

Time Series and Stochastic Processes

Peter Lukianchenko

24 September 2022

Lecture

- ▶ It all starts with the definition of conditional probability:
 $P(A|B) = P(AB)/P(B)$.
- ▶ If X and Y are jointly discrete random variables, we can use this to define a probability mass function for X *given* $Y = y$.
- ▶ That is, we write $p_{X|Y}(x|y) = P\{X = x|Y = y\} = \frac{p(x,y)}{p_Y(y)}$.
- ▶ In words: first restrict sample space to pairs (x, y) with given y value. Then divide the original mass function by $p_Y(y)$ to obtain a probability mass function on the restricted space.
- ▶ We do something similar when X and Y are continuous random variables. In that case we write $f_{X|Y}(x|y) = \frac{f(x,y)}{f_Y(y)}$.
- ▶ Often useful to think of sampling (X, Y) as a two-stage process. First sample Y from its marginal distribution, obtain $Y = y$ for some particular y . Then sample X from its probability distribution *given* $Y = y$.
- ▶ Marginal law of X is weighted average of conditional laws.

$$\mathcal{F}_0 = \{ \emptyset, \Omega \}$$

Lecture

$$\mathcal{F} = \{ \{1\}, \{2\}, \dots, \{6\}, \emptyset, \Omega, \{2,3,4,5,6\}, \{1,3,4,5,6\}, \dots \}$$

- ▶ Let X be value on one die roll, Y value on second die roll, and write $Z = X + Y$.
- ▶ What is the probability distribution for X given that $Y = 5$?
- ▶ Answer: uniform on $\{1, 2, 3, 4, 5, 6\}$.
- ▶ What is the probability distribution for Z given that $Y = 5$?
- ▶ Answer: uniform on $\{6, 7, 8, 9, 10, 11\}$.
- ▶ What is the probability distribution for Y given that $Z = 5$?
- ▶ Answer: uniform on $\{1, 2, 3, 4\}$.

Lecture

$$\begin{aligned} & \{1,2,3,4,5,6\}, \{2,4,6\}, \{1,3,5\} \\ & \{3,5\}, \emptyset, \Omega \end{aligned} \quad \mathcal{F}_{\max} = 2^{\{1,2,3,4,5,6\}} \\ \{\mathcal{F}_t\}_{t \geq 0} \quad t \leq T$$

- ▶ Now, what do we mean by $E[X|Y = y]$? This should just be the expectation of X in the conditional probability measure for X given that $Y = y$

- ▶ Can write this as

$$E[X|Y = y] = \sum_x x P\{X = x|Y = y\} = \sum_x x p_{X|Y}(x|y).$$

- ▶ Can make sense of this in the continuum setting as well.

- ▶ In continuum setting we had $f_{X|Y}(x|y) = \frac{f(x,y)}{f_Y(y)}$. So

$$E[X|Y = y] = \int_{-\infty}^{\infty} x \frac{f(x,y)}{f_Y(y)} dx$$

Lecture

- ▶ Let X be value on one die roll, Y value on second die roll, and write $Z = X + Y$.
- ▶ What is $E[X|Y = 5]$?
- ▶ What is $E[Z|Y = 5]$?
- ▶ What is $E[Y|Z = 5]$?

Lecture

- ▶ Can think of $E[X|Y]$ as a function of the random variable Y . When $Y = y$ it takes the value $E[X|Y = y]$.
- ▶ So $E[X|Y]$ is itself a random variable. It happens to depend only on the value of Y .
- ▶ Thinking of $E[X|Y]$ as a random variable, we can ask what *its* expectation is. What is $E[E[X|Y]]$?
- ▶ **Very useful fact:** $E[E[X|Y]] = E[X]$.
- ▶ In words: what you expect to expect X to be *after learning* Y is same as what you *now* expect X to be.
- ▶ Proof in discrete case:
$$E[X|Y = y] = \sum_x xP\{X = x|Y = y\} = \sum_x x \frac{p(x,y)}{p_Y(y)}.$$
- ▶ Recall that, in general, $E[g(Y)] = \sum_y p_Y(y)g(y)$.
- ▶ $E[E[X|Y = y]] = \sum_y p_Y(y) \sum_x x \frac{p(x,y)}{p_Y(y)} = \sum_x \sum_y p(x,y)x = E[X].$

Lecture

- ▶ Definition:
$$\text{Var}(X|Y) = E[(X - E[X|Y])^2|Y] = E[X^2 - E[X|Y]^2|Y].$$
- ▶ $\text{Var}(X|Y)$ is a random variable that depends on Y . It is the variance of X in the conditional distribution for X given Y .
- ▶ Note $E[\text{Var}(X|Y)] = E[E[X^2|Y]] - E[E[X|Y]^2|Y] = E[X^2] - E[E[X|Y]^2]$.
- ▶ If we subtract $E[X]^2$ from first term and add equivalent value $E[E[X|Y]]^2$ to the second, RHS becomes $\text{Var}[X] - \text{Var}[E[X|Y]]$, which implies following:
- ▶ **Useful fact:** $\text{Var}(X) = \text{Var}(E[X|Y]) + E[\text{Var}(X|Y)]$.
- ▶ One can discover X in two stages: first sample Y from marginal and compute $E[X|Y]$, then sample X from distribution given Y value.
- ▶ Above fact breaks variance into two parts, corresponding to these two stages.

Lecture

- ▶ Let X be a random variable of variance σ_X^2 and Y an independent random variable of variance σ_Y^2 and write $Z = X + Y$. Assume $E[X] = E[Y] = 0$.
- ▶ What are the covariances $\text{Cov}(X, Y)$ and $\text{Cov}(X, Z)$?
- ▶ How about the correlation coefficients $\rho(X, Y)$ and $\rho(X, Z)$?
- ▶ What is $E[Z|X]$? And how about $\text{Var}(Z|X)$?
- ▶ Both of these values are functions of X . Former is just X . Latter happens to be a constant-valued function of X , i.e., happens not to actually depend on X . We have $\text{Var}(Z|X) = \sigma_Y^2$.
- ▶ Can we check the formula $\text{Var}(Z) = \text{Var}(E[Z|X]) + E[\text{Var}(Z|X)]$ in this case?

Lecture

- ▶ Sometimes think of the expectation $E[Y]$ as a “best guess” or “best predictor” of the value of Y .
- ▶ It is best in the sense that among all constants m , the expectation $E[(Y - m)^2]$ is minimized when $m = E[Y]$.
- ▶ But what if we allow non-constant predictors? What if the predictor is allowed to depend on the value of a random variable X that we can observe directly?
- ▶ Let $g(x)$ be such a function. Then $E[(Y - g(X))^2]$ is minimized when $g(X) = E[Y|X]$.

Lecture

- ▶ Toss 100 coins. What's the conditional expectation of the number of heads given the number of heads among the first fifty tosses?
- ▶ What's the conditional expectation of the number of aces in a five-card poker hand given that the first two cards in the hand are aces?

Lecture

Conditional expectation, $\mathbb{E}(X | Y)$, is a random variable with randomness inherited from Y , not X .

$$E[X_{t+1} | \mathcal{F}_t] = X_{t+1}, \quad E[X_t | \mathcal{F}_t] = X_t$$

Lecture

martingale $E[X_{t+1} | \mathcal{F}_t] = X_t$
 sub-martingale $E[X_{t+1} | \mathcal{F}_t] > X_t$
 super-martingale $E[X_{t+1} | \mathcal{F}_t] < X_t$

Example: Suppose $Y = \begin{cases} 1 & \text{with probability } 1/8, \\ 2 & \text{with probability } 7/8, \end{cases}$

and $X | Y = \begin{cases} 2Y & \text{with probability } 3/4, \\ 3Y & \text{with probability } 1/4. \end{cases}$

$$E[X|Y] = 2Y \cdot \frac{3}{4} + 3Y \cdot \frac{1}{4} = \frac{9Y}{4} = \frac{9}{4} \cdot Y$$

$$E_Y[E[X|Y]] = E_Y\left[\frac{9}{4}Y\right] = \frac{9}{4} \cdot \frac{1}{8} + \frac{9 \cdot 2}{4} \cdot \frac{7}{8} = \frac{9 + 9 \cdot 14}{32} = \frac{9 \cdot 15}{32} = E(X)$$

Lecture

Conditional variance

The conditional variance is similar to the conditional expectation.

- $\text{Var}(X | Y = y)$ is the variance of X , when Y is fixed at the value $Y = y$.
- $\text{Var}(X | Y)$ is a random variable, giving the variance of X when Y is fixed at a value to be selected randomly.

Definition: Let X and Y be random variables. The conditional variance of X , given Y , is given by

$$\text{Var}(X | Y) = \mathbb{E}(X^2 | Y) - \left\{ \mathbb{E}(X | Y) \right\}^2 = \mathbb{E} \left\{ (X - \mu_{X|Y})^2 | Y \right\}$$

Lecture

If all the expectations below are finite, then for ANY random variables X and Y , we have:

i) $\mathbb{E}(X) = \mathbb{E}_Y(\mathbb{E}(X | Y))$ *Law of Total Expectation.*

Note that we can pick any r.v. Y , to make the expectation as easy as we can.

ii) $\mathbb{E}(g(X)) = \mathbb{E}_Y(\mathbb{E}(g(X) | Y))$ *for any function g .*

iii) $\text{Var}(X) = \mathbb{E}_Y(\text{Var}(X | Y)) + \text{Var}_Y(\mathbb{E}(X | Y))$

Law of Total Variance.

Lecture

1. Swimming with dolphins

Fraser runs a dolphin-watch business. Every day, he is unable to run the trip due to bad weather with probability p , independently of all other days. Fraser works every day except the bad-weather days, which he takes as holiday.

Let Y be the number of consecutive days Fraser has to work between bad-weather days. Let X be the total number of customers who go on Fraser's trip in this period of Y days. Conditional on Y , the distribution of X is

$$(X | Y) \sim \text{Poisson}(\mu Y).$$

- (a) Name the distribution of Y , and state $\mathbb{E}(Y)$ and $\text{Var}(Y)$.
- (b) Find the expectation and the variance of the number of customers Fraser sees between bad-weather days, $\mathbb{E}(X)$ and $\text{Var}(X)$.

Lecture

(a) *Let ‘success’ be ‘bad-weather day’ and ‘failure’ be ‘work-day’.*

Then $\mathbb{P}(\text{success}) = \mathbb{P}(\text{bad-weather}) = p$.

Y is the number of failures before the first success.

So

$$Y \sim \text{Geometric}(p).$$

Thus

$$\mathbb{E}(Y) = \frac{1-p}{p},$$

$$\text{Var}(Y) = \frac{1-p}{p^2}.$$

Lecture

(b) We know $(X | Y) \sim \text{Poisson}(\mu Y)$: so

$$\mathbb{E}(X | Y) = \text{Var}(X | Y) = \mu Y.$$

By the Law of Total Expectation:

$$\begin{aligned}\mathbb{E}(X) &= \mathbb{E}_Y\left\{\mathbb{E}(X | Y)\right\} \\ &= \mathbb{E}_Y(\mu Y) \\ &= \mu \mathbb{E}_Y(Y)\end{aligned}$$

$$\therefore \mathbb{E}(X) = \frac{\mu(1-p)}{p}.$$

By the Law of Total Variance:

$$\begin{aligned}\text{Var}(X) &= \mathbb{E}_Y\left(\text{Var}(X | Y)\right) + \text{Var}_Y\left(\mathbb{E}(X | Y)\right) \\ &= \mathbb{E}_Y(\mu Y) + \text{Var}_Y(\mu Y) \\ &= \mu \mathbb{E}_Y(Y) + \mu^2 \text{Var}_Y(Y) \\ &= \mu \left(\frac{1-p}{p}\right) + \mu^2 \left(\frac{1-p}{p^2}\right) \\ &= \frac{\mu(1-p)(p+\mu)}{p^2}.\end{aligned}$$

Lecture

2. Randomly stopped sum

This model arises very commonly in stochastic processes. A random number N of events occur, and each event i has associated with it some cost, penalty, or reward X_i . The question is to find the mean and variance of the total cost / reward:

$$T_N = X_1 + X_2 + \dots + X_N.$$

The difficulty is that the number N of terms in the sum is itself random.

T_N is called a *randomly stopped sum*: it is a sum of X_i 's, randomly stopped at the random number of N terms.

Example: Think of a cash machine, which has to be loaded with enough money to cover the day's business. The number of customers per day is a random number N . Customer i withdraws a random amount X_i . The total amount withdrawn during the day is a randomly stopped sum: $T_N = X_1 + \dots + X_N$.

Lecture

Cash machine example

The citizens of Remuera withdraw money from a cash machine according to the following probability function (X):

Amount, x (\$)	50	100	200
$\mathbb{P}(X = x)$	0.3	0.5	0.2

$$E(X) = 105 \quad V(X) = 2725$$

The number of customers per day has the distribution $N \sim \text{Poisson}(\lambda)$.

Let $T_N = X_1 + X_2 + \dots + X_N$ be the total amount of money withdrawn in a day, where each X_i has the probability function above, and X_1, X_2, \dots are independent of each other and of N .

T_N is a randomly stopped sum, stopped by the random number of N customers.

- (a) Show that $\mathbb{E}(X) = 105$, and $\text{Var}(X) = 2725$.
- (b) Find $\mathbb{E}(T_N)$ and $\text{Var}(T_N)$: the mean and variance of the amount of money withdrawn each day.

Lecture

Similarly,

$$\begin{aligned}\text{Var}(T_N | N) &= \text{Var}(X_1 + X_2 + \dots + X_N | N) \\ &= \text{Var}(X_1 + X_2 + \dots + X_N)\end{aligned}$$

where N is now considered constant;

(because all X_i 's are independent of N)

$$= \text{Var}(X_1) + \text{Var}(X_2) + \dots + \text{Var}(X_N)$$

(we DO need independence of X_i 's for this)

$$= N \times \text{Var}(X) \quad (\text{because all } X_i \text{'s have same variance, } \text{Var}(X))$$

$$= 2725N$$

$$E[T_N | N]$$

$$N \cdot E[X] =$$

$$\underline{\underline{N \cdot 105}}$$

$$\text{Var}(T_N) = E_N(\text{Var}(T_N | N)) + \text{Var}_N(E[T_N | N])$$

$$E_N(2725N) = 2725 \times +$$

Lecture

$$\begin{aligned} &= 2725\lambda + \text{Var}_N(105 \cdot N) \\ &= 2725\lambda + 105^2 \lambda \end{aligned}$$

So

$$\begin{aligned} \mathbb{E}(T_N) &= \mathbb{E}_N \left\{ \mathbb{E}(T_N | N) \right\} \\ &= \mathbb{E}_N(105N) \\ &= 105\mathbb{E}_N(N) \\ &= 105\lambda, \end{aligned}$$

because $N \sim \text{Poisson}(\lambda)$ so $\mathbb{E}(N) = \lambda$.

Similarly,

$$\begin{aligned} \text{Var}(T_N) &= \mathbb{E}_N \left\{ \text{Var}(T_N | N) \right\} + \text{Var}_N \left\{ \mathbb{E}(T_N | N) \right\} \\ &= \mathbb{E}_N \{ 2725N \} + \text{Var}_N \{ 105N \} \\ &= 2725\mathbb{E}_N(N) + 105^2 \text{Var}_N(N) \\ &= 2725\lambda + 11025\lambda \\ &= 13750\lambda, \end{aligned}$$

because $N \sim \text{Poisson}(\lambda)$ so $\mathbb{E}(N) = \text{Var}(N) = \lambda$.

$$\sigma_1 \leq \sigma_2 \leq \sigma_3 \leq \sigma_4$$

$$\mathbb{E}[\mathbb{E}[\mathbb{E}[X | \mathcal{F}_1] | \mathcal{F}_2] | \mathcal{F}_3] \dots$$

Lecture

General result for randomly stopped sums:

Suppose X_1, X_2, \dots each have the same mean μ and variance σ^2 , and X_1, X_2, \dots , and N are mutually independent. Let $T_N = X_1 + \dots + X_N$ be the randomly stopped sum. By following similar working to that above:

$$\mathbb{E}(T_N) = \mathbb{E} \left\{ \sum_{i=1}^N X_i \right\} = \mu \mathbb{E}(N)$$

$$\text{Var}(T_N) = \text{Var} \left\{ \sum_{i=1}^N X_i \right\} = \sigma^2 \mathbb{E}(N) + \mu^2 \text{Var}(N).$$
